# Anatomy of the eye

# Anterior chamber I

## Flow mechanisms

### Flow induced by aqueous production/drainage:

Aqueous humor is produced by the ciliary body, and then flows through the posterior chamber, the pupil and the anterior chamber, from where it is drained into the trabecular meshwork. ( $3 \mu\text{l}/\text{min}$ )

### Flow induced during miosis/mydriasis:

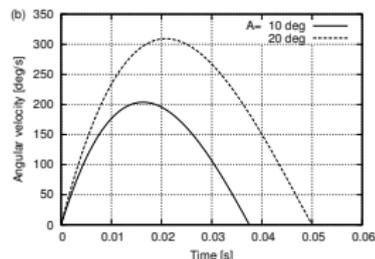

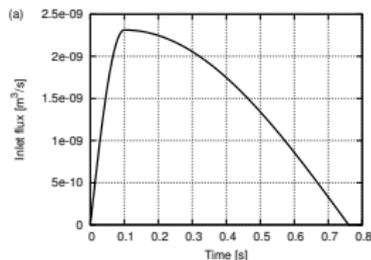

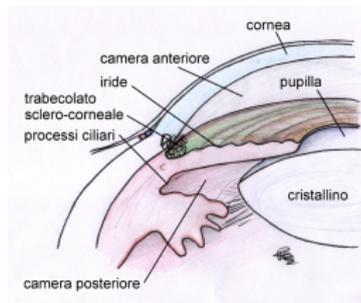

During pupil contraction (miosis), a flow from the posterior to the anterior chamber of the eye is generated, which is intense, although it only lasts a short time, typically less than 1 s. (**middle figure**)

### Buoyancy-driven flow:

It is well known that, since the posterior surface of the cornea is typically cooler than the iris and lens. We prescribed a temperature of  $34^\circ\text{C}$  on the cornea and  $37^\circ\text{C}$  on all other surfaces.

### Flow induced by saccades of the eye:

We consider the flow generated in the anterior chamber by rotations of the eye bulb by modeling isolated rotations using the analytical relationship proposed by Repetto et al. (2005) which provides the angular velocity of the eye as a function of time. (**bottom figure**)

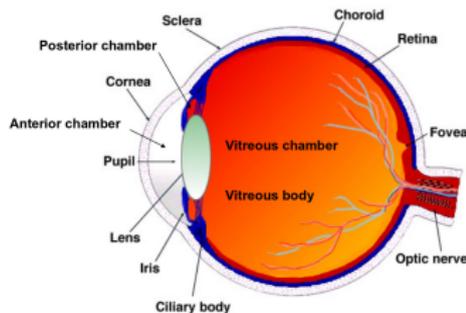

## Vitreous characteristics and functions

### Vitreous composition

The main constituents are

- Water (99%);
- hyaluronic acid (HA);
- collagen fibrils.

Its structure consists of long, thick, non-branching collagen fibrils suspended in hyaluronic acid.

### Normal vitreous characteristics

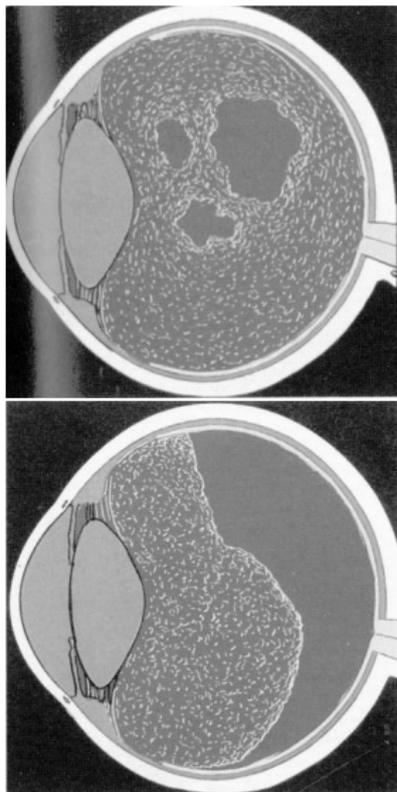

- The healthy vitreous in youth is a gel-like material with **visco-elastic mechanical properties**, which have been measured by several authors (Lee et al., 1992; Nickerson et al., 2008; Swindle et al., 2008).
- In the outermost part of the vitreous, named **vitreous cortex**, the concentration of collagen fibrils and HA is higher.
- The vitreous cortex is in contact with the **Internal Limiting Membrane (ILM)** of the retina.

### Physiological roles of the vitreous

- **Support function for the retina** and filling-up function for the vitreous body cavity;
- **diffusion barrier** between the anterior and posterior segment of the eye;
- establishment of an **unhindered path of light**.

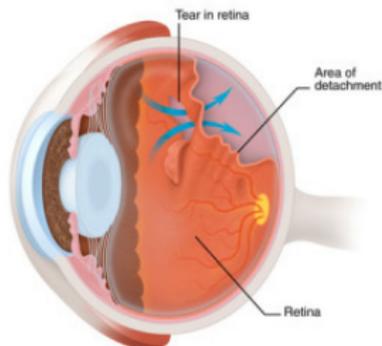

## Vitreous ageing

With advancing age the vitreous typically undergoes significant changes in structure.

- Disintegration of the gel structure which leads to **vitreous liquefaction (synchysis)**. This leads to an approximately linear increase in the volume of liquid vitreous with time. Liquefaction can be as much extended as to interest the whole vitreous chamber.
- Shrinking of the vitreous gel (**syneresis**) leading to the detachment of the gel vitreous from the retina in certain regions of the vitreous chamber. This process typically occurs in the posterior segment of the eye and is called **posterior vitreous detachment (PVD)**. It is a pathophysiologic condition of the vitreous.

# Retinal detachment

## Posterior vitreous detachment (PVD) and vitreous degeneration:

- more common in myopic eyes;
- preceded by changes in vitreous macromolecular structure and in vitreoretinal interface → possibly mechanical reasons.
- If the retina detaches from the underlying layers → loss of vision;

## Rhegmatogenous retinal detachment:

- fluid enters through a retinal break into the sub retinal space and peels off the retina.

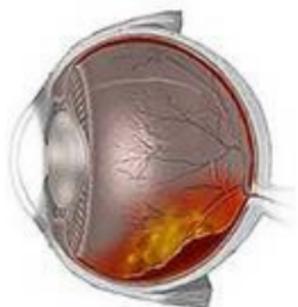

## Risk factors:

- **myopia**;
- posterior vitreous detachment (PVD);
- lattice degeneration;
- ...

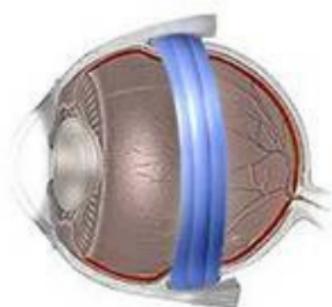

# Scleral buckling and vitrectomy

## Scleral buckling

Before

After

Scleral buckling is the application of a rubber band around the eyeball at the site of a retinal tear in order to promote reattachment of the retina.

## Vitrectomy

The vitreous may be completely replaced with tamponade fluids: silicon oils, water, gas, ..., usually immiscible with the eye's own aqueous humor

# Investigations

# A model for the linear stability of the interface between aqueous humor and vitreous substitutes after vitreoretinal surgery

# Stability of the interface between aqueous humor and vitreous substitutes after vitreoretinal surgery

## Retinal detachment

Warning signs of retinal detachment:

- Flashing lights.
- Sudden appearance of floaters.
- Shadows on the periphery of your vision.
- Gray curtain across your field of vision.

## Vitrectomy

The vitreous may be completely replaced with tamponade fluids: silicon oils, air, gas, ...

- Denoted **tamponade liquids**
- Purpose: Induce an instantaneous interruption of an open communication between the subretinal space/retinal pigment epithelial cells and the pre-retinal space.
- Healing: a scar should form as the cells absorb the remaining liquid.

## Fluids commonly used as a vitreous substitutes

- **Silicone oils;**

- $960 \leq \rho^* \leq 1290 \text{ kg/m}^3$
- $10^{-4} \leq \nu^* \leq 5 \times 10^{-3} \text{ m}^2/\text{s}$
- $\sigma^* \approx 0.05 \text{ N/m}$

- **Perfluorocarbon liquids;**

- $1760 \leq \rho^* \leq 2030 \text{ kg/m}^3$
- $8 \times 10^{-7} \leq \nu^* \leq 8 \times 10^{-6} \text{ m}^2/\text{s}$
- $\sigma^* \approx 0.05 \text{ N/m}$

- **Semifluorinated alkane liquids;**

- $1350 \leq \rho^* \leq 1620 \text{ kg/m}^3$
- $4.6 \times 10^{-4} \leq \nu^* \leq 10^{-3} \text{ m}^2/\text{s}$
- $0.035 \leq \sigma^* \leq 0.05 \text{ N/m}$

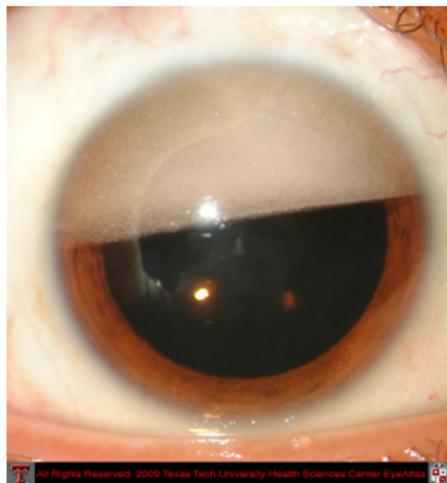

The choice of tamponade liquid depends on the specific case

- The tabulated fluids are **immiscible** with water and commonly used in surgery
- A lighter fluid (cf. water) is used to tamponade in the upper part
- A heavier fluid is used to tamponade in the lower part
- High surface tension is preferred to a low value (**EXPERIENCE**)
- High value of viscosity (cf. water) is preferred to a low value (**EXPERIENCE**)

**What could happen otherwise ?**

# Emulsification

Emulsification leads to loss of vision, **not satisfactory**

**Figure:** Emulsification of vitreous substitutes in the vitreous chamber

# Summary & Motivation

## Summary

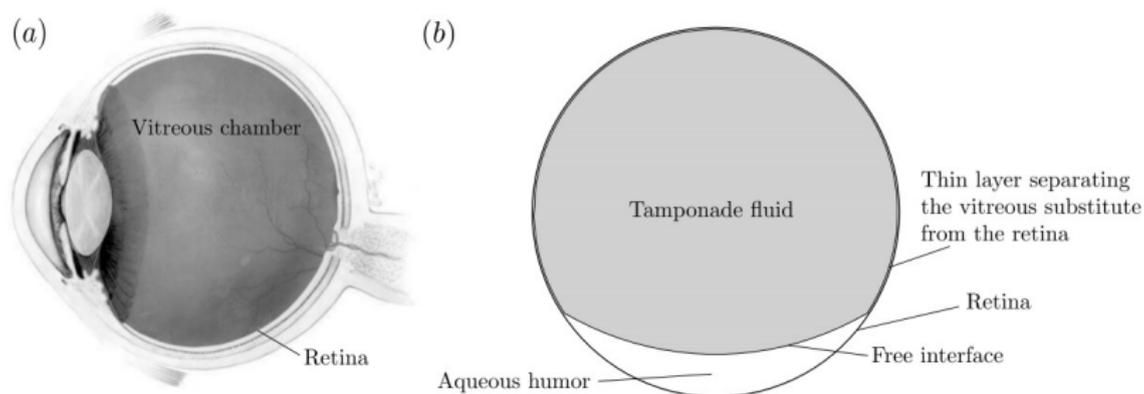

- From **experience** it is known that tamponade fluids with **high surface tension** and **high viscosity** (compared to water) are less prone to emulsify
- It is also known that initially "good" tamponade fluids tend to change with time, for instance a decrease of surface tension due to **surfactants**, which leads to emulsification.
- It is generally believed that **shear stresses** at the tamponade fluid-aqueous **interface** generated during eye rotations play a crucial role in the generation of an emulsion.
- The tamponade liquid needs to stay for a period of months so it is of interest to know how emulsification can be avoided.

## Our analysis

- We want to understand how emulsification, or the initial stages leading to emulsification, are related to the parameters (surface tension, viscosity, density, real conditions).
- As a first study we focus on the **stability characteristics of the interface** in order to see if it has any role.
- A linear stability analysis, of wave like solutions, is used.
- The evolution of the disturbance kinetic energy is analyzed.

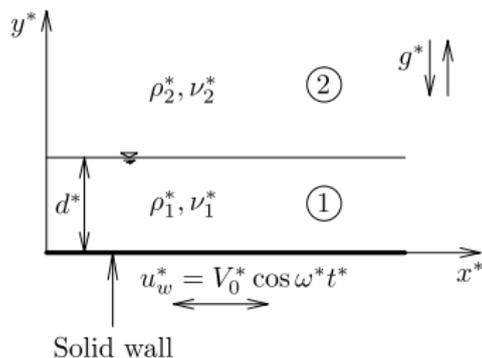

# Mathematical model I

## The geometry

## Mathematical model II

### Underlying assumptions

**Figure:** Geometry of the problem

- $d^* \ll R^*$
- 2D-model;
- flat wall oscillating harmonically;
- semi-infinite domain;
- small perturbations;
- quasi-steady approach.
- Stokes problem when  $\{\}_{1} = \{\}_{2}$

# Scaling and Dimensionless Parameters

$$\mathbf{x} = \frac{\mathbf{x}^*}{d^*}, \quad \mathbf{u}_i = \frac{\mathbf{u}_i^*}{V_0^*}, \quad p_i = \frac{p_i^*}{\rho_1^* V_0^{*2}}, \quad t = \frac{V_0^*}{d^*} t, \quad \omega = \frac{d^*}{V_0^*} \omega^*$$

$$m = \frac{\mu_2^*}{\mu_1^*}$$

$$\gamma = \frac{\rho_2^*}{\rho_1^*}$$

$$Re = \frac{V_0^* d^*}{\nu_1^*}$$

$$Fr = \frac{V_0^*}{\sqrt{g^* d^*}}$$

$$S = \frac{\sigma^*}{\rho_1^* d^* V_0^{*2}}$$

## Basic flow

### Analytical solution

Parallel time-dependent flow

$$U_1(y, t) = (c_1 e^{-ay} + c_2 e^{ey}) e^{i\omega t} + c.c.,$$

$$U_2(y, t) = c_3 e^{-by} e^{i\omega t} + c.c.,$$

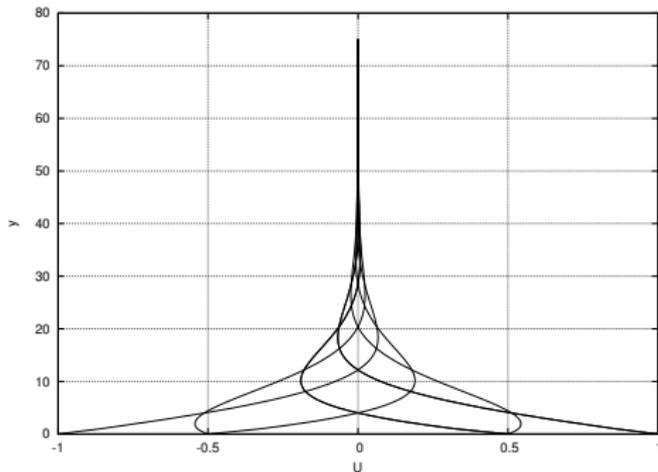

$$\frac{\partial P_1}{\partial y} = -Fr^{-2},$$

$$\frac{\partial P_2}{\partial y} = -\gamma Fr^{-2},$$

where

$$a = \sqrt{i\omega R}, \quad b = \sqrt{\frac{i\gamma\omega R}{m}}.$$

and  $c_1, c_2, c_3$  are functions of  $a, b, m$ .

## Linear stability analysis

Flow decomposition:

$$u_i = U_i + u_i', \quad v_i = v_i' \quad p_i = P_i + p_i'$$

Boundary conditions:

$$u_1'(0, t) = v_1'(0, t) = 0 \quad \text{and} \quad u_2'(y, t) \rightarrow 0, \quad v_2'(y, t) \rightarrow 0 \quad \text{as} \quad y \rightarrow \infty$$

Interface: ( $y^* = d^*$ ) introducing also the perturbation of the interface  $\eta'$

- Continuity of the perturbation velocity components across the interface
- Continuity of the tangential stress of across the interface
- The wall normal stress is balanced by the surface tension

A quasi-steady approach is assumed with two-dimensional wave-like solutions as:

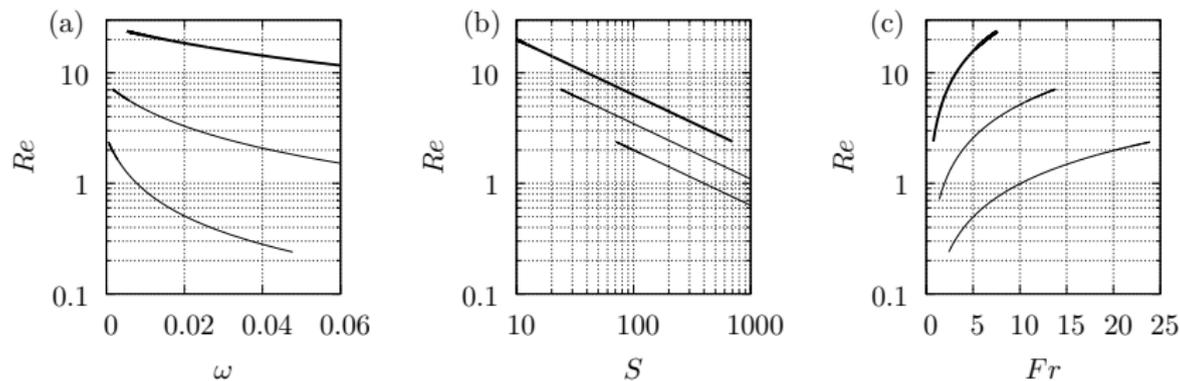

$$\xi_i = e^{i\alpha(x-\Omega t)} \hat{\xi}_i(y, \tau) + c.c$$

where

$$0 \leq \tau \leq 2\pi/\omega$$

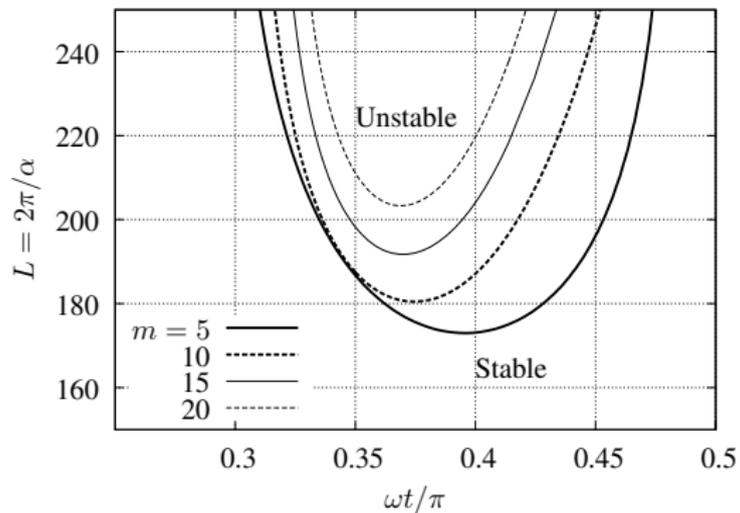

The system of equations is reduced introducing the perturbation stream function giving **two Orr-Sommerfeld equations**, discretized using finite differences, solved using an inverse iteration algorithm.

## Range of variability of the dimensionless parameters

**Figure:** Relationship between  $Re - \omega$ ,  $Re - S$  and  $Re - Fr$  obtained adopting feasible values of eye movement. From thin to thick curves:  $d = 1 \times 10^{-5} \text{ m}$ ,  $d = 3 \times 10^{-5} \text{ m}$ ,  $d = 1 \times 10^{-4} \text{ m}$

## Neutral Curves

**Figure:**  $S = 14$ ,  $\gamma = 1.0$ ,  $Re = 7$ ,  $\omega = 0.001$

## Energy analysis

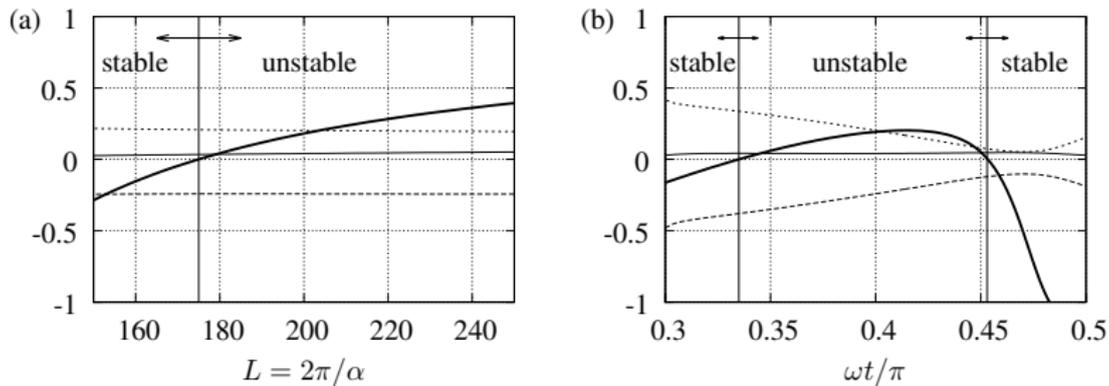

The disturbance kinetic energy is given by 3 contributions: production, dissipation and interface related terms

$$\begin{aligned}
 \frac{\alpha}{2\pi} \frac{dE}{dt} = & - \int_0^1 u_1 v_1 U_1' dy - \gamma \int_1^{+\infty} u_2 v_2 U_2' dy \\
 & - \frac{1}{Re} \int_0^1 \left[ \left( \frac{\partial u_1}{\partial x} \right)^2 + \left( \frac{\partial u_1}{\partial y} \right)^2 + \left( \frac{\partial v_1}{\partial x} \right)^2 + \left( \frac{\partial v_1}{\partial y} \right)^2 \right] dy \\
 & - \frac{m}{Re} \int_1^{+\infty} \left[ \left( \frac{\partial u_2}{\partial x} \right)^2 + \left( \frac{\partial u_2}{\partial y} \right)^2 + \left( \frac{\partial v_2}{\partial x} \right)^2 + \left( \frac{\partial v_2}{\partial y} \right)^2 \right] dy \\
 & \left( v_1 \left[ (\gamma - 1) Fr^{-2} + \alpha^2 S \right] \eta - \frac{v_1}{Re} \left( \frac{\partial v_1}{\partial y} - m \frac{\partial v_2}{\partial y} \right) + \frac{1}{Re} \left( u_1 \frac{\partial u_1}{\partial y} - m u_2 \frac{\partial u_2}{\partial y} \right) \right) \Big|_{y=1}. \quad (4)
 \end{aligned}$$

The different contributions of (4) are commonly presented in terms of growth rates. The sum can directly be compared with the solution of the eigenvalue problem governing the linear stability problem.

$$\frac{1}{2\alpha E} \frac{dE}{dt} = \text{Im}(\Omega).$$

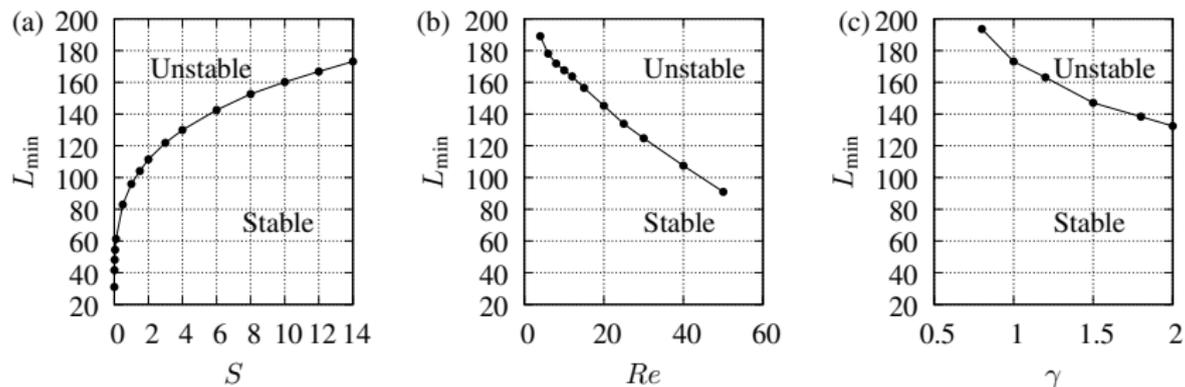

## Results from the energy analysis

**Figure:** The different contributions from the energy analysis as a function of (a)  $L$  for  $\omega t/\pi = 0.4$  (a) and (b)  $\omega t/\pi$  for  $L = 200$ . In both figures  $S = 14$ ,  $\gamma = 1.0$ ,  $R = 7$ ,  $m = 5$ ,  $\omega = 0.001$ . Lines: thin solid (production), dashed (dissipation), dotted (interface), thick solid (growth rate scaled).

# Shortest unstable wave length

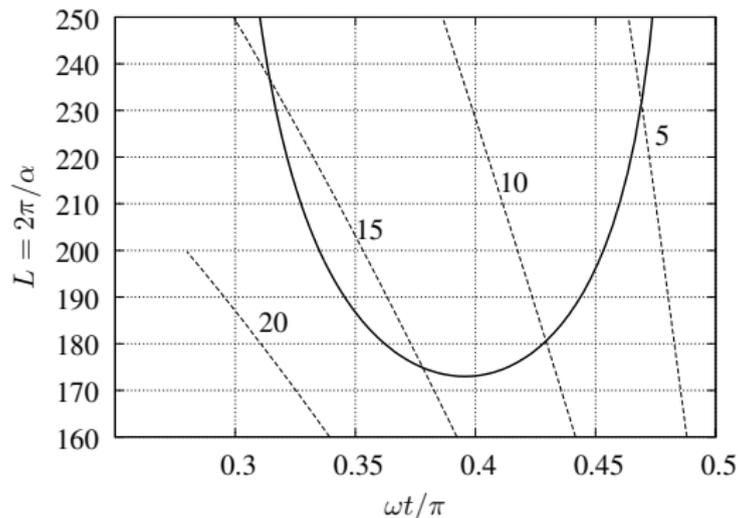

The **shortest** unstable wave length as a function of  $S$ ,  $Re$  and  $\gamma$ .

**Figure:** Length of the shortest unstable perturbation  $L_{min}$  versus  $S$  (a),  $Re$  (b), and  $\gamma$  (c) with  $\omega = 0.001$  and  $m = 5$ . The values of  $Re = 7$  in (a) and (c),  $S = 14$  in (b) and (c), and  $\gamma = 1$  in (a) and (b), respectively.

## Verification of the quasi-steady approach

In order for the quasi steady approach to be valid the perturbation frequency should be larger than the base flow frequency (scale separation).

**Figure:** Neutral stability curve (solid line) in the  $(\omega t/\pi) - L$  plane for the case  $m = 5$ ,  $Re = 7$ ,  $\omega = 0.001$ ,  $S = 14$ ,  $\gamma = 1$ . The dotted lines show the values of the ratio  $\alpha \Re(\Omega)/\omega$ .

## Conclusions and Continuation

### Monitoring the shortest unstable wave length (critical wave length) we have seen that:

- Increasing the viscosity, ratio the critical wave length increases (**stabilizing for the Eye**)
- Increasing the surface tension, the critical wave length increases (**stabilizing for the Eye**)
- Increasing the Reynolds no., the critical wave length decreases (**destabilizing for the Eye**)
- Increasing the density ratio, the critical wave length decreases (**destabilizing for the Eye**)
- The first two is "in line" with realistic observations.
- For realistic values of  $R, S, \gamma, m, \omega, d^*$  the critical wave length  $\approx 5$  mm, which is about half the Eye radius.
- However, the growth rate is instantaneous and the waves unstable only during certain intervals of one period. (cf. turbulent burst in the classical Stokes II problem). No sustained growth over one period is guaranteed.
- This analysis is far from explaining the onset of emulsion but a first step to rule out (or not) different physical mechanisms.

### Next step...

- Floquet analysis
- Non-modal analysis
- Include curvature, ....., more realistic geometry (circle, sphere)

## Phakic iris-fixated intraocular lens placement in the anterior chamber: effects on aqueous flow

R. Repetto<sup>1</sup>, J. O. Pralits<sup>1</sup>, J. H. Siggers<sup>2</sup> and P. Soleri<sup>3</sup>

Published: *investigative ophthalmology & visual science (iovs)* 2015; 56(5):3061-3068.

## Flow of aqueous humour with an intraocular lens

### Phakic intraocular lenses

### Motivation

Intraocular lenses decrease endothelial cell density in some patients. Possible reasons include:

- Excess shear stress due to altered flow of aqueous
- Impaired transport of nutrients due to altered flow
- Non-ideal placement of lens, with respect to iris and other tissues
- Impact of external body on eye (e.g. accidental impact, patient touching eyes)

**This study:** Investigate the first possibility, by comparing the shear stress both in the presence of and without the lens. Moreover, monitor the intra-ocular pressure (IOP).

# Description of the model

## Governing equations:

$$\nabla \cdot \mathbf{u} = 0$$

$$\rho \left( \frac{\partial \mathbf{u}}{\partial t} + \mathbf{u} \cdot \nabla \mathbf{u} \right) = -\nabla p + \nabla^2 \mathbf{u} + \rho \mathbf{g}$$

$$\rho c_p \left( \frac{\partial T}{\partial t} + \mathbf{u} \cdot \nabla T \right) = k_a \nabla^2 T$$

## Assumptions:

- Boussinesq approximation ( $\rho$  is constant, except in the gravitational acceleration term in which  $\rho = \rho_0(1 - \alpha(T - T_0))$ )

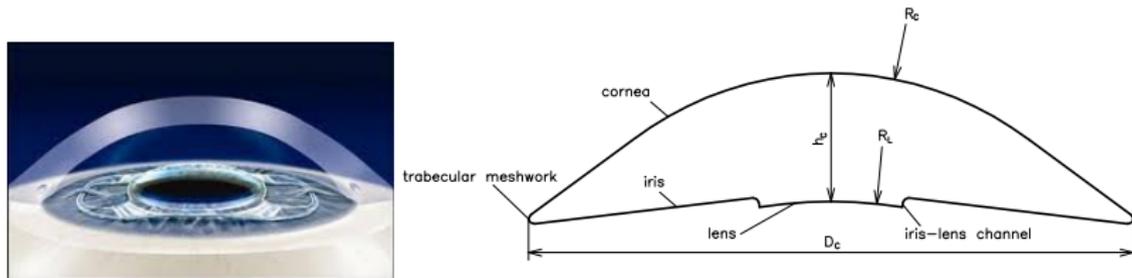

## Numerical solution:

- All solutions are obtained with *OpenFOAM*
- Solvers were first tested on cases where analytical solutions exist.

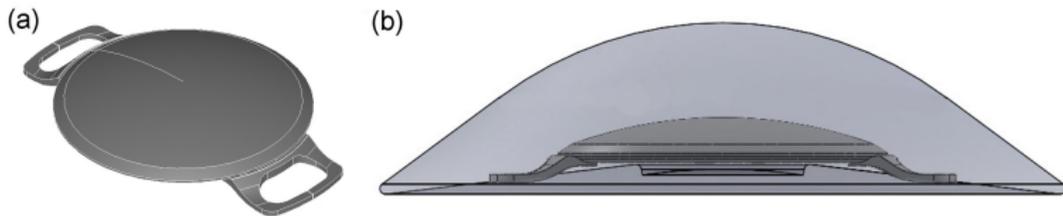

## Definitions:

Symbol	Definition
$\mathbf{u}$	velocity
$p$	pressure
$\rho$	density of aqueous
$\mu$	viscosity of aqueous
$\mathbf{g}$	acceleration due to gravity
$c_p$	specific heat at constant pressure
$T$	temperature
$k_a$	thermal conductivity of aqueous

# Model geometry

**Figure:** (left) "real" anterior chamber, (right) cross-section of the idealized anterior chamber used in the simulations.

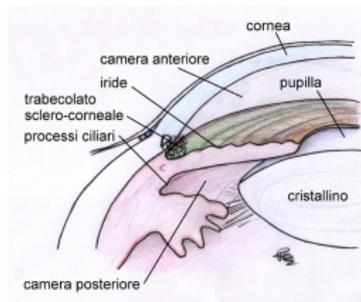

**Figure:** (a) Geometry of the pIOL consisting of a lens and two haptics that have claws that allow the lens to be attached to the iris, (b) pIOL placed in the anterior chamber.

# Flow mechanisms

## Flow induced by aqueous production/drainage:

Aqueous humor is produced by the ciliary body, and then flows through the posterior chamber, the pupil and the anterior chamber, from where it is drained into the trabecular meshwork. ( $3 \mu\text{l}/\text{min}$ )

## Flow induced during miosis:

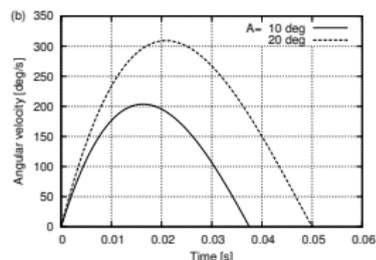

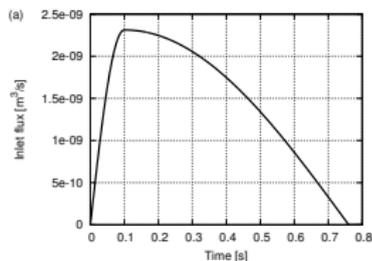

During pupil contraction (miosis), a flow from the posterior to the anterior chamber of the eye is generated, which is intense, although it only lasts a short time, typically less than 1 s. (middle figure)

## Buoyancy-driven flow:

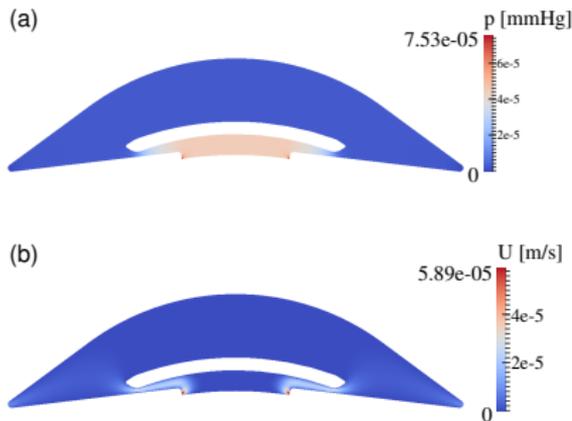

It is well known that, since the posterior surface of the cornea is typically cooler than the iris and lens. We prescribed a temperature of  $34^\circ\text{C}$  on the cornea and  $37^\circ\text{C}$  on all other surfaces.

## Flow induced by saccades of the eye:

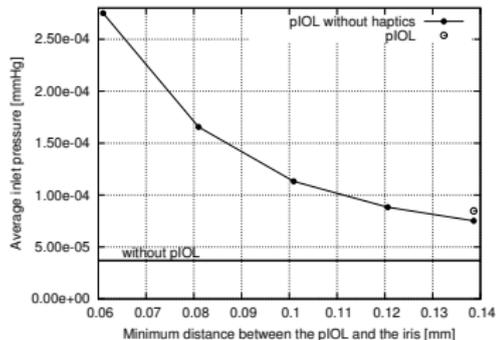

We consider the flow generated in the anterior chamber by rotations of the eye bulb by modeling isolated rotations using the analytical relationship proposed by Repetto et al. (2005) which provides the angular velocity of the eye as a function of time. (bottom figure)

## Flow induced by aqueous production and drainage

**Figure:** Flow due to production/drainage of aqueous humor with the device present: (a) excess pressure above IOP, (b) velocity magnitude.

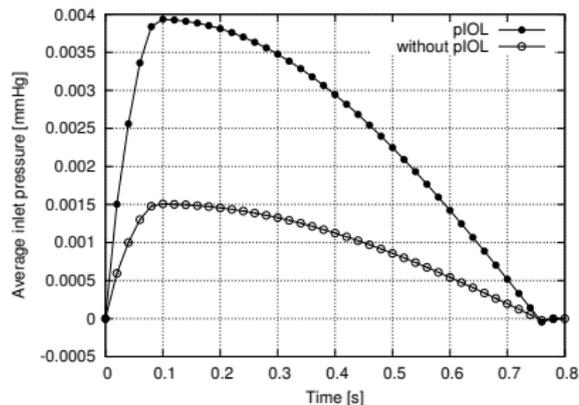

**Figure:** Average pressure drop between iris–lens channel and trabecular meshwork as a function of the minimum distance between the pIOL and the iris (solid circles). No pIOL (horizontal line) and pIOL with haptics (empty circle).

Lubrication theory:

$$\Delta p = \frac{6\mu Q}{\pi} \int_{r_1}^{r_2} \frac{dr}{rh^3},$$

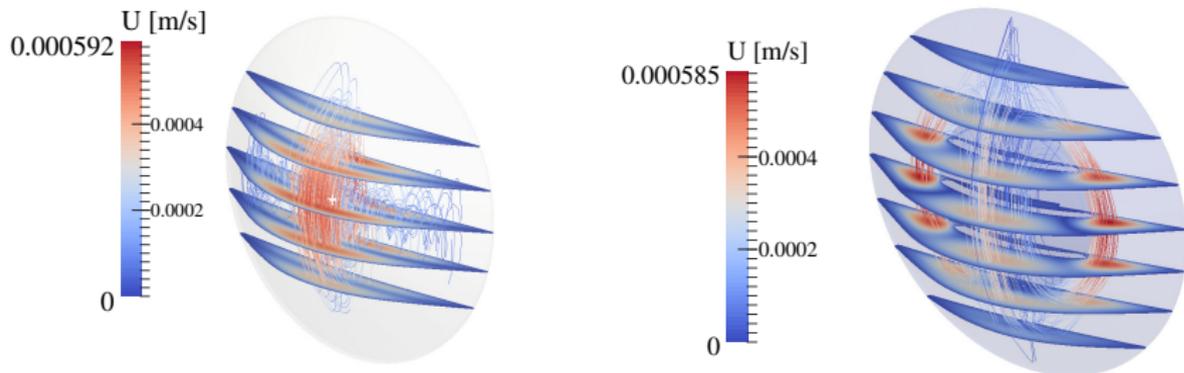

To get  $\Delta p = 1 \text{ mmHg}$  you need  $h = 1 \mu\text{m}$

# Flow induced during miosis

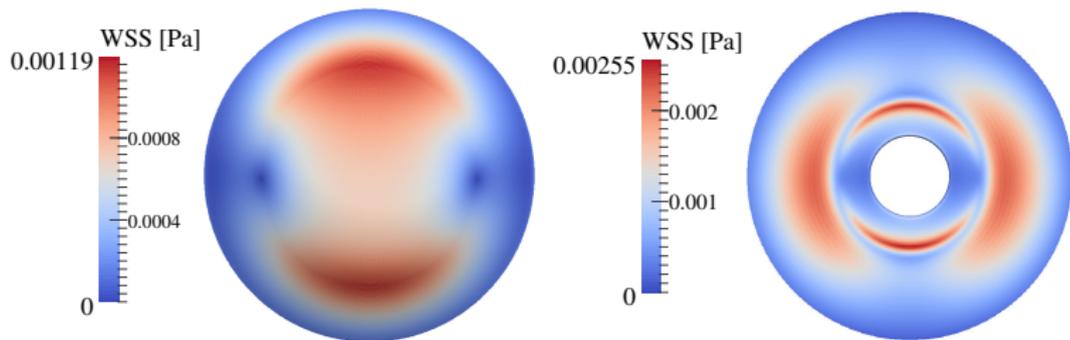

**Figure:** Spatially averaged pressure over the inlet as a function of time during miosis, in an eye both with the pIOL (solid circles) and without it (open circles).

# Buoyancy-driven flow I

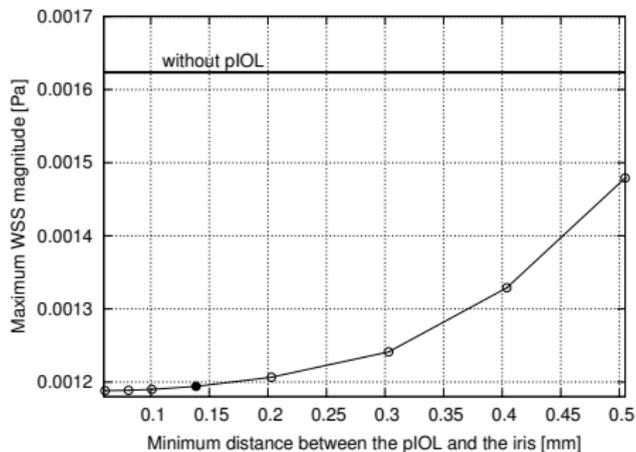

**Figure:** Buoyancy-driven flow in the absence of the pIOL. Gravity acts in the vertical direction. Streamlines of the flow and the distribution of the velocity magnitude on selected horizontal planes, (a) without the lens, (b) with the lens.

## Buoyancy-driven flow II

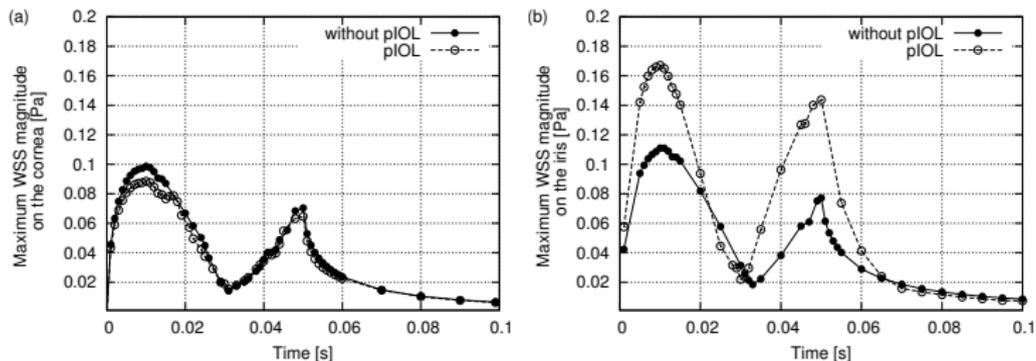

**Figure:** Buoyancy-driven flow in the presence of the pIOL. (a) Magnitude of WSS on the cornea; (b) WSS on the iris.

## Buoyancy-driven flow III

**Figure:** Spatial maximum of the WSS on the cornea as a function of the distance between the pIOL and the iris, neglecting the haptics (open circles). The maximum WSS with no pIOL is shown by the horizontal line, whilst the maximum WSS with the pIOL in its normal position and including the haptics is shown by the solid circle.

# Flow induced by saccades of the eye

**Figure:** Time evolution of the spatial maximum of the WSS on the (a) cornea and (b) iris in an eye performing a saccade of angle  $10^\circ$ .

## Discussion and conclusions

- (i) If the lens is properly placed there is a negligible influence on the pressure in the posterior chamber.
- (ii) There is no significant increase of the WSS on the cornea.
- (iii) The WSS on the iris is significantly greater than in the case with no pIOL, but the increase is not likely to be sufficiently great so as to give a risk of cell detachment.

### Endothelial cell loss:

- Kaji et al.(2005) performed experiments on porcine corneal endothelial cells that were plated onto glass slides, and found that significant detachment was observed for shear stresses in excess of 0.03 Pa if the cells had had 1 hour of adhesion, rising to 0.1 Pa for 3 hours of adhesion. Our model predicts that the actual values are significantly smaller than this.
- Other causes: **rubbing** the eye (mechanical forcing), insufficient delivery of oxygen **and/or nutrients** to the corneal epithelium. The latter will be studied in the near future.

## Computer modeling of rhegmatogenous retinal detachment

A paper is in preparation for *investigative ophthalmology & visual science (iops)*

# Retinal break

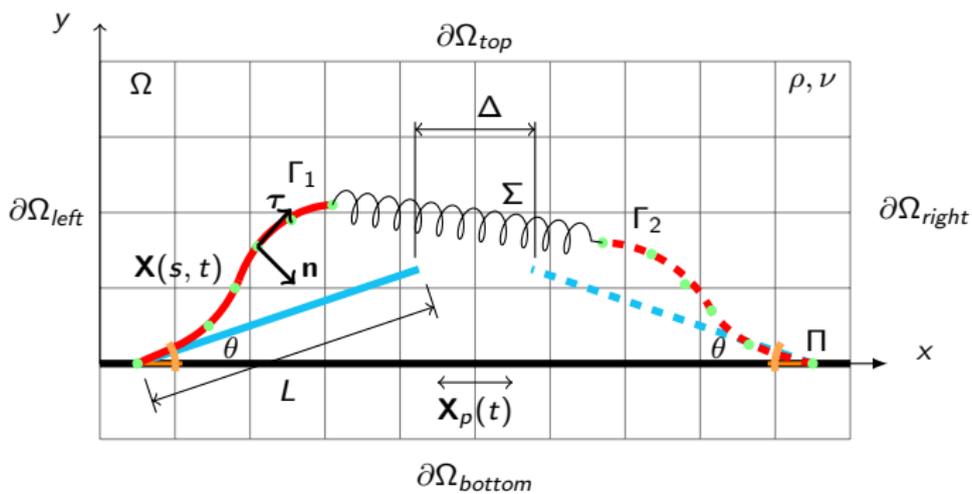

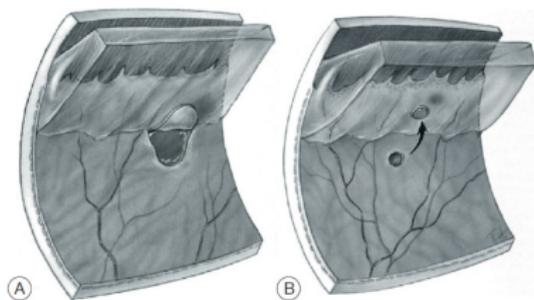

## Rhegmatogenous retinal detachment

- Occurs in approximately **1 in 10,000** of the population.
- Caused by the appearance of retinal **breaks in the peripheral retina**
- Unchecked retinal detachment is a **blinding condition**
- There is uncertainty surrounding the mechanism of action of surgical methods.
- **Traction on the retina** from separation of the vitreous is thought to create the retinal break
- Postulated that **saccadic eye movements** create liquefied vitreous flow in the eye, which help to lift the retina.
- Experience says that the **hole** condition detaches quicker than the **free flap** condition

**Here:** use numerical simulations (**FSI**) to investigate the two cases under realistic conditions to give indications to surgeons.

## The model

## The model parameters

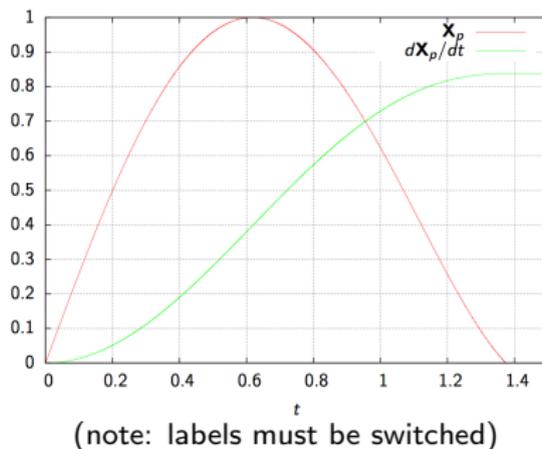

Quantity	Value	Reference
<b>Properties of the retinal flap</b>		
Density $\rho_S$	1300 kg/m <sup>3</sup>	
Length $L$	1.5 – 2.5 mm	yes
Thickness	70 $\mu\text{m}$	yes
Bending stiffness $K_b$	$2.98 \cdot 10^{-11}$ Nm <sup>2</sup>	
Young modulus $E$	$1.21 \cdot 10^3$ N/m <sup>2</sup>	yes
<b>Properties of the fluid</b>		
Density $\rho_F$	1000 kg/m <sup>3</sup>	yes
Dynamic viscosity $\mu$	$1.065 \cdot 10^{-3}$ kg/ms	yes

**Table:** Parameter values used for the simulations.

- thickness/length =  $h/L = 1/30$
- The flap is considered a slender body,  $K_b = Eh^3/12$
- Curvature neglected but the vitreous chamber radius  $\approx 12$  mm
- It is known that the retina is slightly heavier than the aqueous humor, here  $\rho_S/\rho_F = 1.3$

## The saccadic eye movement

**Saccade:** Ballistic, conjugate, voluntary eye movements that change the point of foveal fixation.

- The saccade is modeled by a fifth polynomial, in Repetto et al. (2005)
- angle is  $8^\circ$
- The maximum velocity is 0.061 m/s
- The duration is 0.045 s

## The mathematical model

$$\begin{cases} \frac{\partial \mathbf{u}}{\partial t}(\mathbf{x}, t) + \mathbf{u}(\mathbf{x}, t) \cdot \nabla \mathbf{u}(\mathbf{x}, t) = -\nabla p(\mathbf{x}, t) + \frac{1}{Re} \nabla^2 \mathbf{u}(\mathbf{x}, t) + \mathbf{f}(\mathbf{x}, t) \\ \nabla \cdot \mathbf{u}(\mathbf{x}, t) = 0 \end{cases} \quad (5)$$

$$\mathbf{F}_{imp} = \alpha \int_0^t (\mathbf{U}_{ib} - \frac{\partial \mathbf{X}}{\partial t}) dt' + \beta (\mathbf{U}_{ib} - \frac{\partial \mathbf{X}}{\partial t}) \quad (6)$$

$$\mathbf{F} = (\mathbf{F}_{imp} \cdot \mathbf{n}) \mathbf{n} + (\mathbf{F}_{imp} \cdot \boldsymbol{\tau}) \boldsymbol{\tau} \quad (7)$$

$$\mathbf{f}(\mathbf{x}, t) = \rho \int_{\Gamma} \mathbf{F}(s, t) \delta(\mathbf{x} - \mathbf{X}(s, t)) ds \quad (8)$$

$$\mathbf{U}_{ib}(s, t) = \int_{\Omega} \mathbf{u}(\mathbf{x}, t) \delta(\mathbf{x} - \mathbf{X}(s, t)) d\Omega \quad (9)$$

$$\frac{\partial^2 \mathbf{X}}{\partial t^2} = \frac{\partial}{\partial s} \left( T \frac{\partial \mathbf{X}}{\partial s} \right) - \frac{\partial^2}{\partial s^2} \left( \gamma \frac{\partial^2 \mathbf{X}}{\partial s^2} \right) + Fr \frac{\mathbf{g}}{g} - \mathbf{F} \quad (10)$$

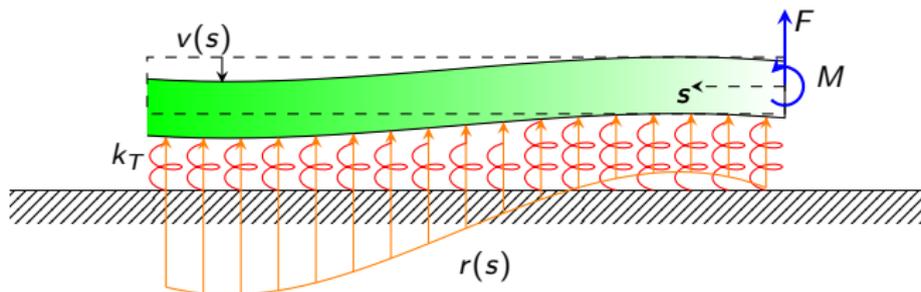

$$\frac{\partial \mathbf{X}}{\partial s} \frac{\partial^2}{\partial s^2} \left( T \frac{\partial \mathbf{X}}{\partial s} \right) = \frac{1}{2} \frac{\partial^2}{\partial t^2} \left( \frac{\partial \mathbf{X}}{\partial s} \frac{\partial \mathbf{X}}{\partial s} \right) - \frac{\partial^2 \mathbf{X}}{\partial t \partial s} \frac{\partial^2 \mathbf{X}}{\partial t \partial s} - \frac{\partial \mathbf{X}}{\partial s} \frac{\partial}{\partial s} (\mathbf{F}_b - \mathbf{F}) \quad (11)$$

along with suitable boundary conditions.

## The tendency to detach

From the solution of the FSI problem we can evaluate the forces  $\mathbf{F} = (F_{c,\tau}, F_{c,n})$  and the moment  $M_c$  at the clamping point(s). However, this static forces need to be combined in order to obtain an overall **tendency to detach**.

Here we use, from civil engineering, the **Winkler's theory**. The theory assumes that the substrate on which the retina adheres can be thought of as a system of identical, independent, closely spaced, discrete and linearly elastic springs

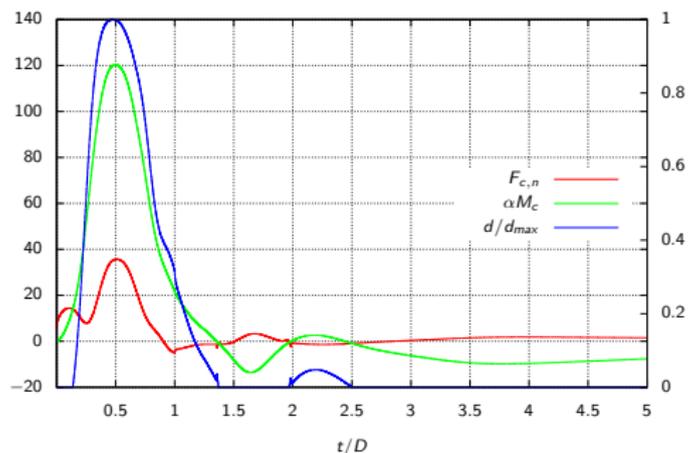

$$v(0) = \frac{\alpha M_c + F_{c,n}}{2\alpha^3 I E}, \quad \text{and} \quad d = \max(v(0), 0),$$

where  $\alpha \approx 40$  is the ratio between the stiffness of the substrate to the bending stiffness of the foundation beam (retina).

## Results I

In all cases  $Re = 114.6$  based on maximum velocity and  $L = 2\text{mm}$ .

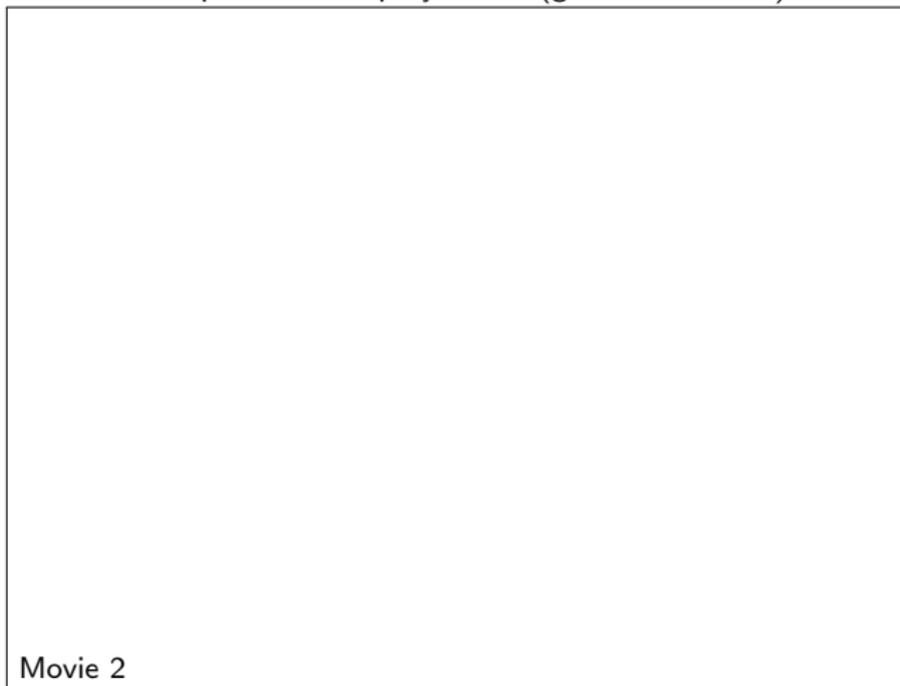

Here, an example of the temporal variation of the wall-normal clamping force, moment and tendency to detach  $d$ .

**Figure:** The normal component of the clamping force  $F_{c,n}$  together with the clamping moment  $M_c$  multiplied by the parameter  $\alpha$  on the left vertical axis and the tendency to detach  $d/d_{max}$  on the right vertical axis as a function of the dimensionless time  $t/D$ . Note that  $d \sim \alpha M_c + F_{c,n}$ . In this case  $L = 2\text{ mm}$  and  $\theta = 33.56^\circ$ .

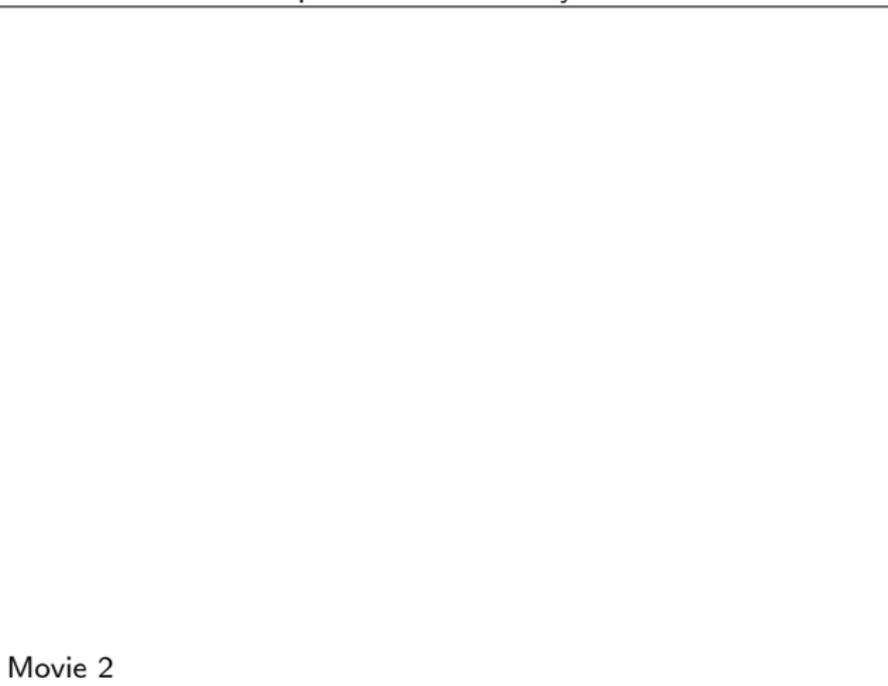

## Results II

Example of free-flap dynamics (giant retinal tear)

## Results III

Exampel of retinal hole dynamics

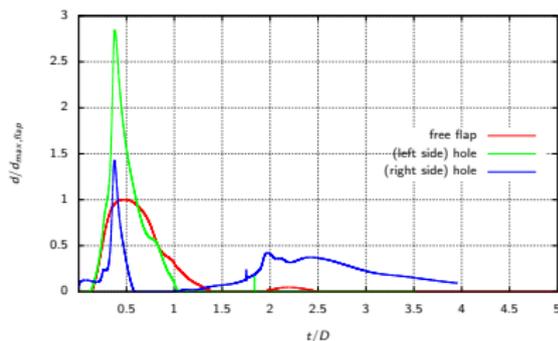

## Results IV

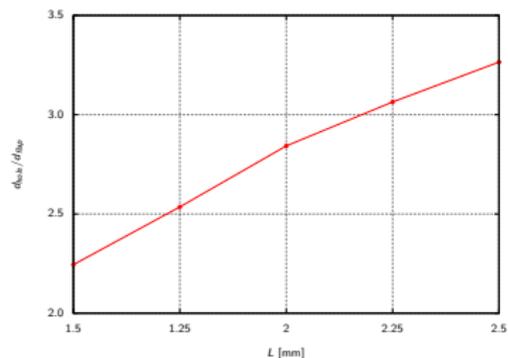

### Free flap vs. retinal hole

Experience tells that the retinal hole is more prone to further detach compared to the free flap.

$L = 2\text{mm}$ ,  $\theta = 33.56^\circ$ , and  $\Delta = 0.17\text{mm}$ .

Maximum value of  $d_{hole}/d_{flap}$  as a function of  $L$

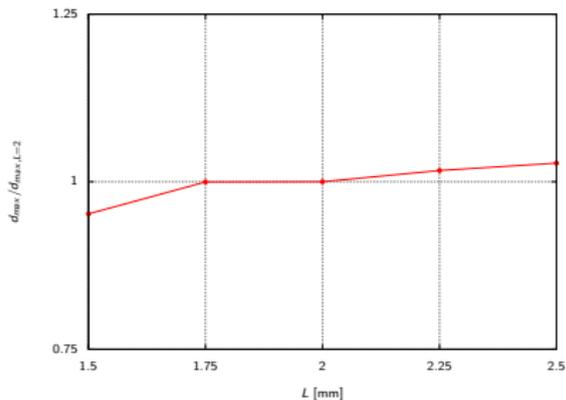

The numerical simulations are giving similar trends as what has been observed clinically with an increasing trend for increasing values of the retinal length.

## Results V

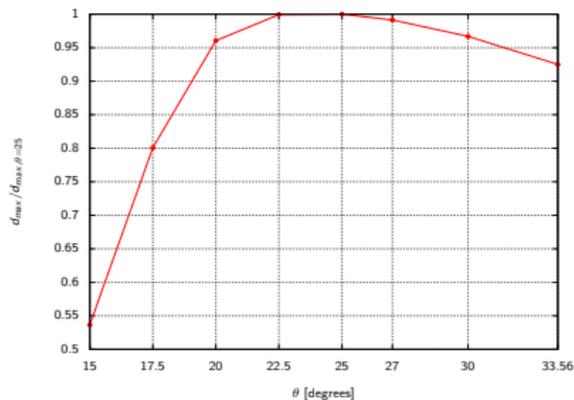

### Results regarding the free-flap case

#### Effect of changing the length $L$

Increasing tendency with increasing values of  $L$

#### Effect of changing the clamping angle $\theta$

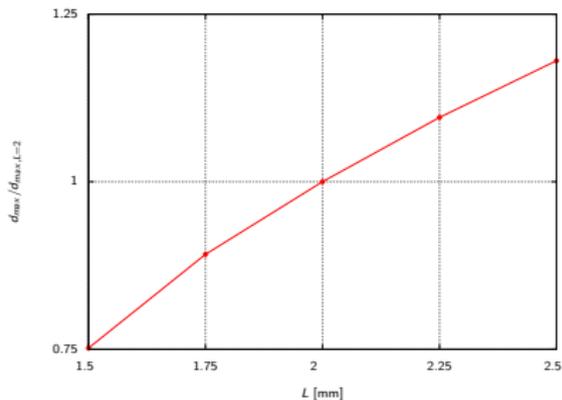

A maximum tendency is found for  $\theta \approx 25^\circ$

## Results VI

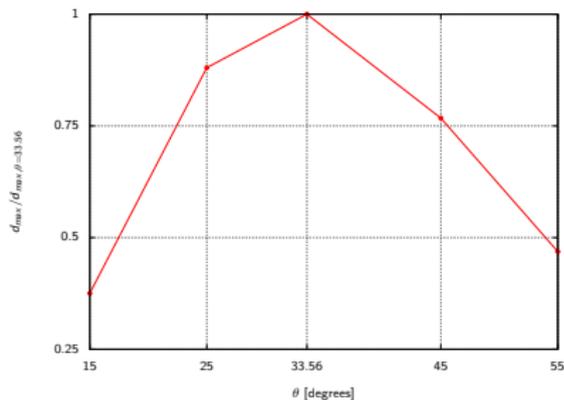

### Results regarding the retinal hole

#### Effect of changing the length $L$

Increasing tendency with increasing values of  $L$

#### Effect of changing the clamping angle $\theta$

A maximum tendency is found for  $\theta \approx 34^\circ$

## Conclusions

The tendency to detach has been analyzed both for the **free flap** and **hole case** for different values of the detached retinal length, clamping angle and inter-tip distance (in the case of retinal hole). The general conclusions can be summarized as follows:

- The tendency to detach of a retinal hole, compared to a retinal free flap, is 2 - 3 times larger for retinal filaments of 1.5 - 2.5 mm, with increasing values of  $d$  for increasing values of the filament length.
- The tendency to detach increases as the retinal filament length increases, both for the retinal hole- and retinal free flap case.
- A worst-case angle is found when the tendency to detach is investigated for different clamping angles. The value is  $\simeq 25^\circ$  in the free flap case and  $\simeq 34^\circ$  in the hole case.
- The effect of changing the inter-tip distance, which is related to the size of the retinal hole, on the tendency to detach is weak.

## Equilibrium shape of the aqueous humour-vitreous substitute interface

A paper is in preparation for *investigative ophthalmology & visual science (iops)*

## Equilibrium shape

Tamponade fluids (TF) used for vitrectomy are immiscible with aqueous humor (AH) and a small pocket of AH is therefore created between the TF and the retina. Knowing the shape of the interface and where the TF is in contact with the retina is **important information for the surgeons**.

The purpose here is to **predict with a numerical model the shape of the interface between aqueous humor and tamponade fluids** in the vitreous chamber, in the case of use of a gas or a silicon oil. To determine the retinal coverage in the case of various eye shapes, from **normal** to highly **myopic eyes**.

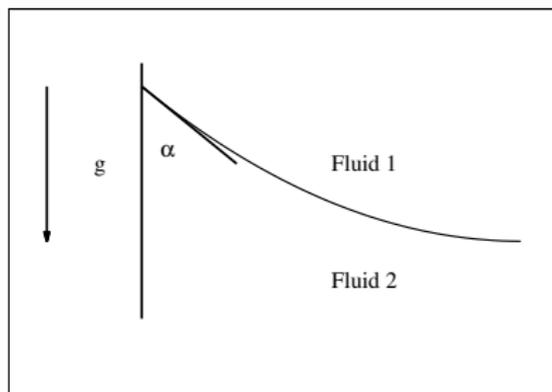

The eye geometry has been taken from Atchison and Smith (2000) and the myopic eye is elongated in all directions and dimensions are taken from Atchison et al. (2004).

## Mathematical model

From the Laplace-Young equation

$$2k_m = -\frac{\Delta\rho g}{\gamma}y_i + B,$$

we see that the interface  $y_i$  depends on the **density difference**  $\Delta\rho$ , **surface tension**  $\gamma$ . The constant  $B$  can be found imposing the **contact angle**  $\alpha$  at the solid boundary.

## Mechanical properties of tamponade fluids

In this study we analyze both gas and silicone oil, both used in surgery, with values taken from the literature.

<b>Fluid</b>	<b>Density (kg/m<sup>3</sup>)</b>	<b>Surface tension with aqueous (N/m)</b>	<b>Contact angle with the retina (deg)</b>
Silicone oil	980	0.044	$16.17 \pm 1.23$
Intraocular gas	$\approx 1$	0.07	$30.74 \pm 4.24$
Aqueous humour	1000	-	-

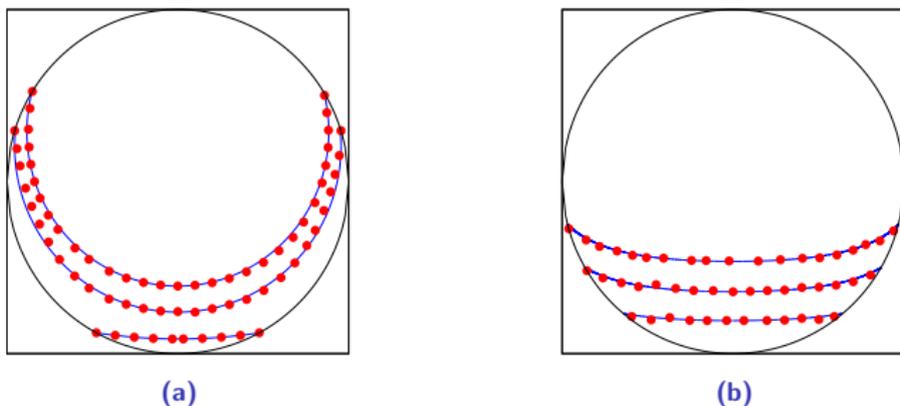

## Numerical model

The numerical, three-dimensional steady solution is obtained using the OpenFOAM, in particular

- VoF method: to keep track of the liquid-liquid interface or gas-liquid interface
- snappyHexMesh: to generate the mesh (not efficient but simple)
- a normal mesh has about 1.7M volumes and we run on a 32 processor work station
- we integrate the governing equations in time and "tune" the viscosity for numerical efficiency

## Validation of the numerical model

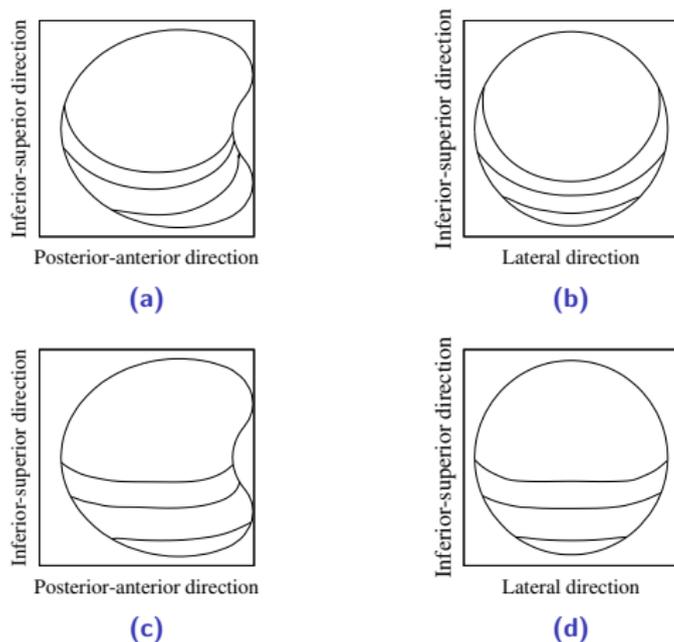

The numerical code was first validated for the case of sphere by comparing the results with those obtained by solving, analytically, the Laplace-Young equation.

**Figure:** Shape of the interface in the spherical domain computed by analytical model (lines) and by the numerical model (dots) for different volume fraction of tamponade fluids: silicone oil (a) and intraocular gas (b).

# Results I

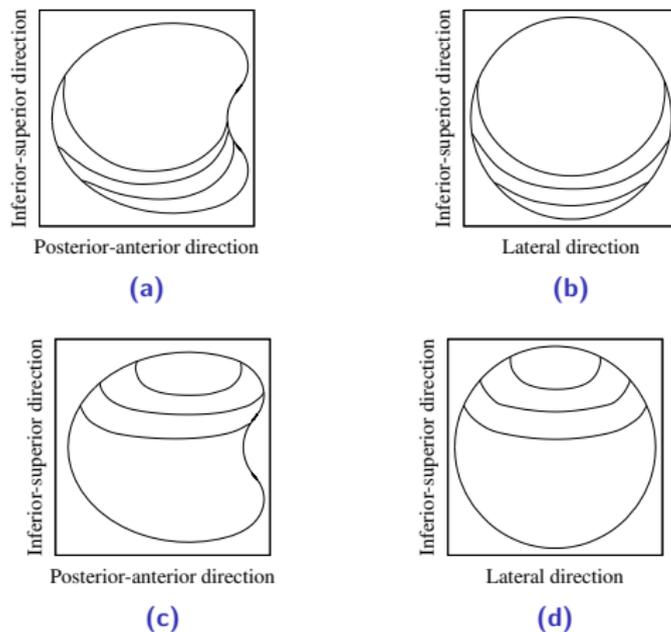

## Emmetropic (normal) eyes

**Figure:** Interface in the normal eye for the silicone oil (a)-(b) and gas (c)-(d). Three different degrees of filling - 90%, 75% and 60% for the silicone oil and 40%, 25% and 10% for the intraocular gas.

## Results II

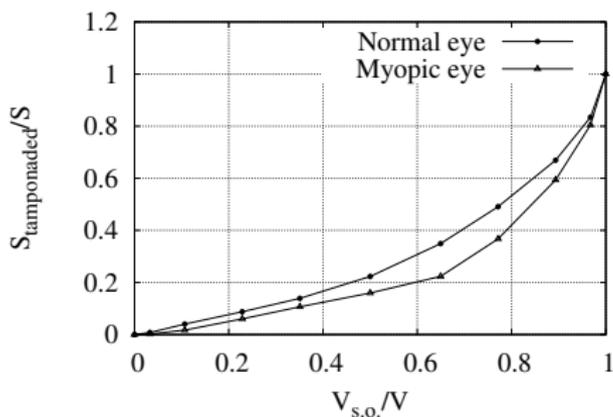

### Myopic eyes

**Figure:** Interface in the myopic eye for the silicone oil (a)-(b) and gas (c)-(d). (a),(c) Intersection normal to lateral direction; (b),(d) intersection normal to anterior-posterior direction. Axial length is 26.6 mm, height and width are 22.75 mm.

## Results III

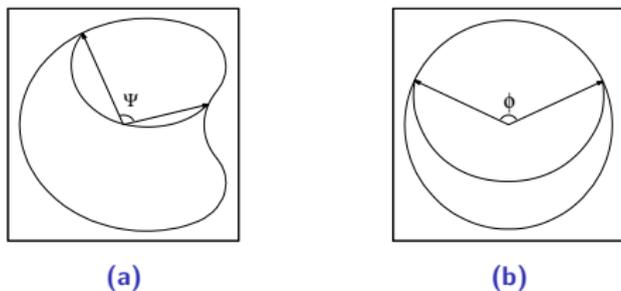

### Comparison normal and myopic eyes (surface)

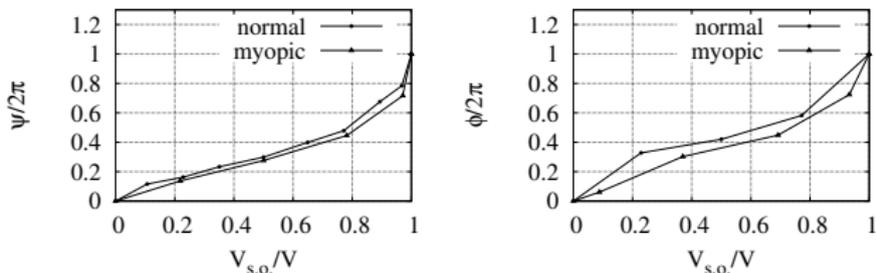

**Figure:** Tamponaded surface of the retina as a function of the volume fraction for the case of silicon oil.

## Results IV

### Comparison normal and myopic eyes (angle)

**Figure:** Measurements of the coverage angle (a) normal to lateral direction and (b) normal to anterior-posterior direction

**Figure:** Coverage angles  $\Psi$  and  $\Phi$  versus the filling ration  $V_{s.o.}/V$  in the case of silicon oil.
